Dermabrasion
is an abrasive process performed to remove the epidermis and
superficial dermis. It results in a smoothing of contour
irregularities. It is often very useful in the treatment of facial
wrinkles, acne scarring, and traumatic scars.

Dermabrasion can be performed in the office under local anesthesia with
sedation or under general anesthesia. The procedure usually takes less
than an hour to perform and can be done in conjunction with other
procedures.

Dr. Wigoda uses dermabrasion most often for the treatment of perioral
wrinkles (around the mouth) and for the treatment of acne scars.
Recovery is often quicker and less painful than laser treatment for
similar problems. Deep wrinkles around the mouth or deep acne scars can
be significantly improved, if not completely removed. The results are
excellent. The treated skin will typically look pink for the first week
and then fade to normal skin color over the next few weeks.
